

Sorghum grown under poor management

Compaction of soil with tracking animals and tractors

Use of poor seeds

No hedges to protect the soil from erosion by wind

Burning of crop residues or overgrazing of harvested fields

Poor weed management

Poor pest and disease management

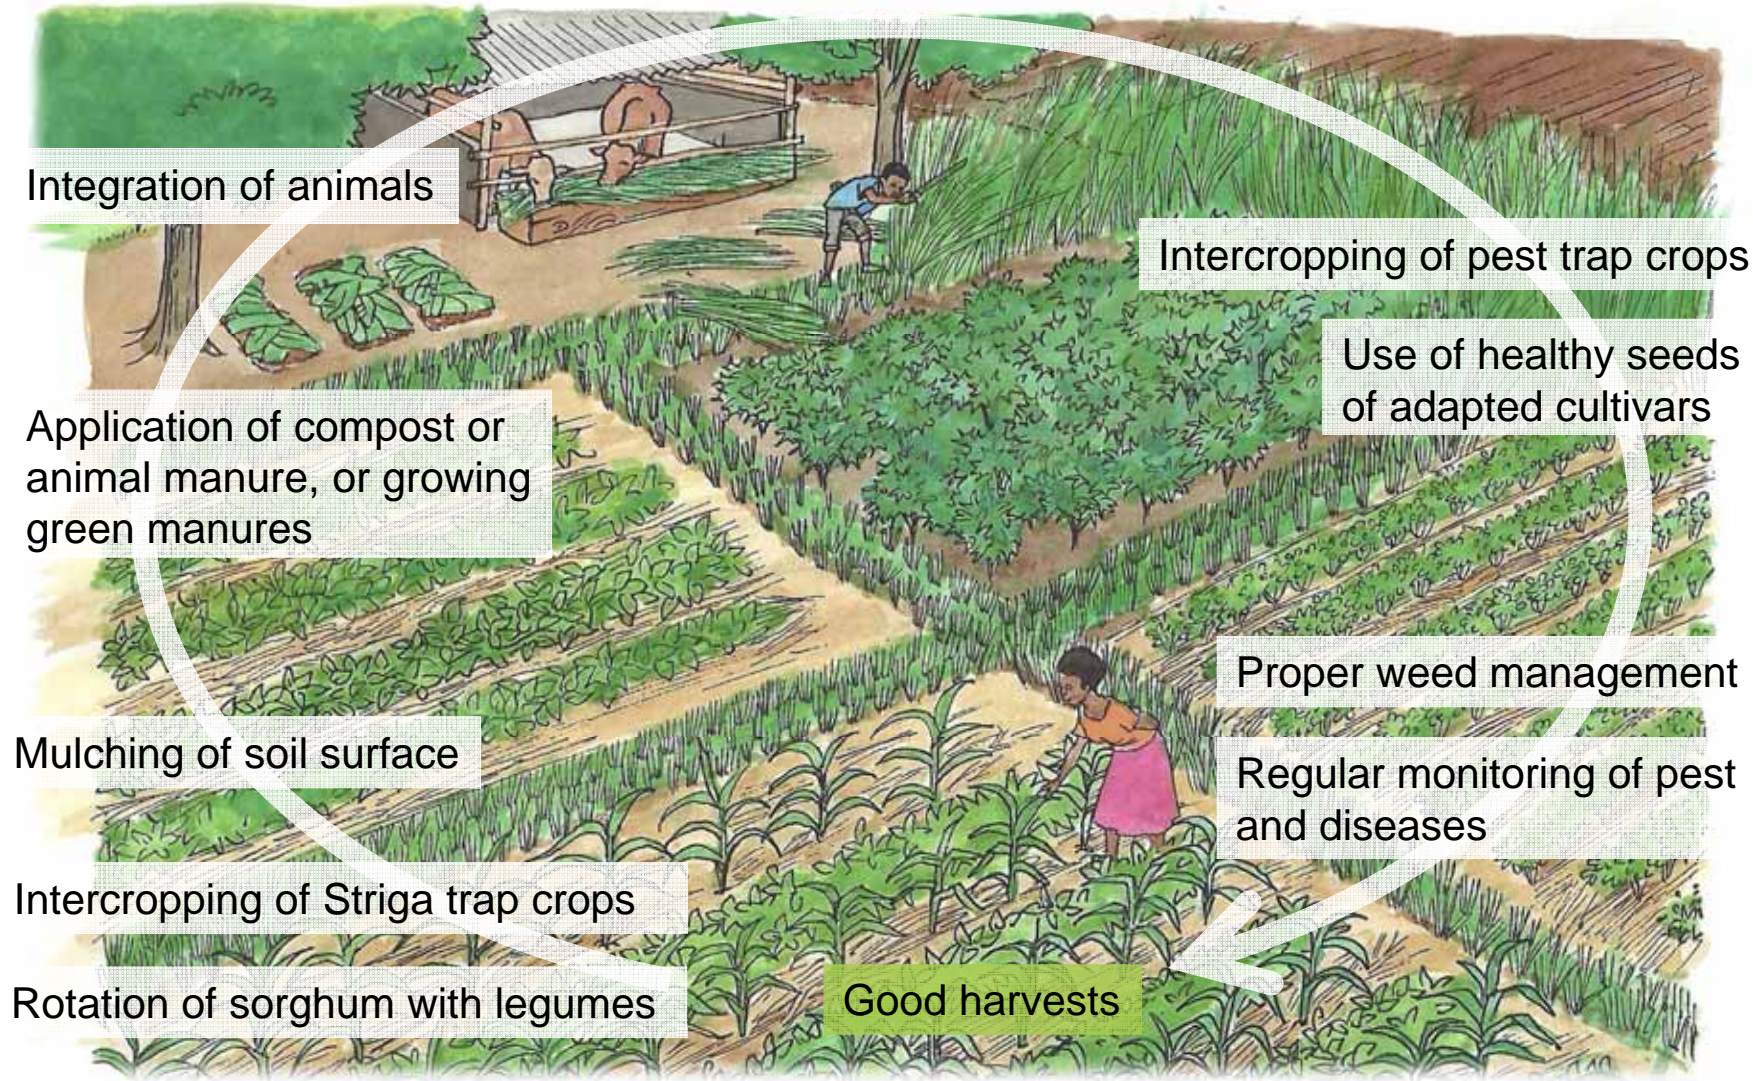

No cover crops or mulches to conserve water in the soil

Continuous planting of sorghum season after season

Poor harvests

Improved cultivation of sorghum

Integration of animals

Intercropping of pest trap crops

Use of healthy seeds of adapted cultivars

Application of compost or animal manure, or growing green manures

Proper weed management

Mulching of soil surface

Regular monitoring of pest and diseases

Intercropping of Striga trap crops

Rotation of sorghum with legumes

Good harvests

Selection of appropriate cultivars

Criteria for selecting sorghum cultivars

- › Type corresponding to the intended use
- › Adapted to local growing conditions
- › Tolerance to the main local pests and diseases like leaf diseases, green bugs, sorghum midge, stemborers, panicle feeding bugs
- › Early and uniform maturity
- › Dual purpose with good grain and good stover yields to provide fodder for livestock also
- › Grain quality that corresponds to processing requirements and consumer preferences

How to ensure good nutrition of sorghum

Blind harrowing

- › Controlling weeds between sowing and crop emergence

In ploughed fields with bare soil weeds can be controlled using a tine weeder.

After emergence of the weeds, but before emergence of the crop weeds are removed with a tine weeder.

False seedbed

1. Prepare the seedbed early (2 to 4 weeks before seeding or planting).

2. Wait until the weeds have emerged.

3. Destroy the weeds at intervals of 7 to 10 days using a tine-weeder.

How to control Striga effectively

Using clean crop seeds only

Uprooting and burning Striga at the beginning of flowering

Intercropping trap crops

Avoiding dispersal of Striga seeds during crop harvest

Rotating host and non-host crops

Improving soil fertility

Few Striga, better crop growth

How to improve water supply of sorghum

Planting hedges as wind barriers

Practicing reduced soil cultivation

Collecting water in trenches or ditches

Covering the soil surface with mulch or appropriate intercrops

Using early maturing and drought tolerant cultivars

Planting early in the season

Controlling stemborer with the push-pull method

2. Plant 2 to 3 rows of healthy Napier grass around the plots before the rain season at 75 cm between rows and 50 cm within rows
3. Sow repelling intercrops together with sorghum
4. Weed intercrops repeatedly

Control of major diseases of sorghum

Diseases	Symptoms	Control measures
Stalk rot	<ul style="list-style-type: none"> › Rotting of roots and premature death › Infected stalk tissue turns dark red › Lodging of plants 	<ul style="list-style-type: none"> › Crop rotation › Use resistant cultivars › Proper spacing
Anthracnose	<ul style="list-style-type: none"> › Orange, red- or blackish purple leaves › Small leaves with circular or elliptical shape 	<ul style="list-style-type: none"> › Use resistant cultivars (hybrids) › Rotation with pulses › Encourage decomposition of crop residues after harvest
Smuts	<ul style="list-style-type: none"> › Sorghum kernels are replaced by a cone-shaped gall (Covered kernel smut) › Long and pointed galls formed by loose kernels (Loose kernel smut) › Large, dark-brown smut galls emerging in place of the panicle (Head smut) 	<ul style="list-style-type: none"> › Use resistant cultivars or certified disease-free seeds › Hot water treatment of seeds › Crop rotation with non-cereals › Removal of infected panicles
Downy mildew	<ul style="list-style-type: none"> › Vivid green and white stripes on the leaves and heads › Heads partially or completely sterile 	<ul style="list-style-type: none"> › At least 3 years between two sorghum or maize crops › Use of resistant cultivars › Use of clean, properly dried seeds › Proper plant spacing

Control of major pests of sorghum

Pests	Preventive and cultural measures	Direct control
Shoot fly	<ul style="list-style-type: none"> › Use of tolerant cultivars (for late planting mainly) › Early, uniform sowing at high seeding rates › Intercropping of legumes (non-host plants) › Removal of wild grass species › Incorporation of crop residues into the soil 	<ul style="list-style-type: none"> › Removal and destruction of infested plants › Spraying of <i>Bacillus thuringiensis</i> against larvae › Spraying of Neem solution against larvae
Stemborer	<ul style="list-style-type: none"> › Early sowing › Intercropping of repelling plants › Promotion of natural enemies › Planting of Napier grass as a trap crop › Destruction of infected crop residues after the harvest 	<ul style="list-style-type: none"> › Application of a Neem- or a fish bean plant extract sawdust/clay mixture into the funnel of young plants
Sorghum midge	<ul style="list-style-type: none"> › Early and uniform sowing with high densities › Use of resistant cultivars › Crop rotation and intercropping with pulses › Removal of host weed species › Incorporation of crop residues after harvest 	<ul style="list-style-type: none"> › Spraying of pyrethrum extract
